

Code Associated with: Hierarchical Bayesian models for small area estimation of county-level private forest landowner population

Neil R. Ver Planck, Andrew O. Finley, Emily S. Huff

August 1, 2017

Introduction

This R Markdown file gives a reproducible example for a single iteration of the small area estimation (SAE) models described in *Hierarchical Bayesian models for small area estimation of county-level private forest landowner population* for Montana. The code can easily be modified and rerun for the example iteration of New Jersey by assigning NJ to the object `state`.

The `MCMCpack` and `coda` packages will need to be loaded in order to access the inverse gamma distribution and summarize the Markov chain Monte Carlo (MCMC) posterior samples. We will also need to `source` the SAE model R scripts for the Fay-Herriot (`FH.R`) and Fay-Herriot conditional autoregressive (`FHCAR.R`) models.

The data image (`data.RData`) loads the following objects:

- `dat`: data frame with columns for
 - `STATE`: character, MT for Montana and NJ for New Jersey
 - `COUNTYNUMB`: integer, county identification number
 - `NAME`: character, county name
 - `iterate`: integer, iteration number of the 4000 simulation runs
 - `n`: numeric, county sample size
 - `Y.i`: numeric, county-level population direct estimate
 - `sigma.sq.i`: numeric, sampling error of direct estimate
- `R.mt`: matrix, neighborhood for Montana lattice
- `R.nj`: matrix, neighborhood for New Jersey lattice
- `X`: data frame with columns for
 - `STATE`: as defined for `dat`
 - `COUNTYNUMB`: as defined for `dat`
 - `POPDEN2010`: numeric, 2010 decennial Census population density (people / km²)
 - `Forest.ha`: numeric, total forest area in hectares
- `Ytrue`: data frame with columns for
 - `STATE`: as defined for `dat`
 - `COUNTYNUMB`: as defined for `dat`
 - `Y.T`: numeric, GIS derived true private forest ownerships

```
library(MCMCpack) ##function for inverse gamma distribution
library(coda)

# source the two SAE models
source("FH.R")
source("FHCAR.R")

# load the data from the R image
load("data.RData")
```

Constants

Each state is analyzed separately, so the first step is to choose the state to be analyzed either MT (for Montana) or NJ (for New Jersey) and the respective neighborhood matrix (i.e., `R.mt` or `R.nj`) defined as `R`. Three MCMC chains are run for each model with a length (`G`) of 3100 and burn-in period (`B`) of 100. The object `sub` is then created to extract post burn-in samples.

```
# Choose the state to analyze (i.e., MT or NJ)
state <- "MT"
#state <- "NJ"

# Select the correct neighborhood matrix (i.e., R.mt or R.nj)
R <- R.mt
#R <- R.nj

# length of each chain
G <- 3100
# burn-in
B <- 100

# post burn-in samples were not thinned
sub <- seq(B+1, G, by = 1)

# set the random seed for reproducibility
set.seed(19)
```

Distributions and additional functions

The multivariate normal distribution is used for drawing from the respective parameters in the SAE model R scripts. The function `quant` is defined for summarizing the 95% credible intervals for parameters of interest.

```
# Multivariate Normal Distribution
rmvn <- function(n, mu=0, V = matrix(1)){
  p <- length(mu)
  if(any(is.na(match(dim(V),p))))
    stop("Dimension problem!")
  D <- chol(V)
  t(matrix(rnorm(n*p), ncol=p)%*%D + rep(mu,rep(n,p)))
}

# Median; 95% Credible Interval
quant <- function(x){quantile(x, prob=c(0.5, 0.025, 0.975))}
```

Subset Data for a Single State

We now subset the `dat`, `Ytrue`, and `X` data frames for the state of interest. The object `m` is also defined for the number of counties for the state of interest. The following additional objects are also created for running the SAE models:

- `logy`: the log transformed direct estimates
- `tilde.sigma.sq`: the transformed sampling errors by the delta method
- `lm.beta`: linear model with `POPDEN2010` and `Forest.ha` covariates
- `beta.start`: beta starting values for the first chain based on `lm.beta`

```

dat.sub <- dat[dat$STATE == state,]

Ytrue <- Ytrue[Ytrue$STATE == state,]

# number of counties
m <- nrow(dat.sub)

# Confirms the covariates are ordered sequentially by county number
X <- X[X$STATE == state, ]
X <- X[order(X$COUNTYNUMB, decreasing = FALSE),]
X <- as.matrix(X[,c("POPDEN2010", "Forest.ha")], nrow = m)
# Design Matrix
X <- cbind(1, X)

y <- as.matrix(dat.sub$Y.i, nrow = m)
logy <- log(y)
tilde.sigma.sq <- as.numeric(dat.sub$sigma.sq.i / y^2)

lm.beta <- lm(logy ~ -1 + X)
beta.start <- as.matrix(coef(lm.beta), nrow = 3)

```

SAE Models

We now run three chains for the FH SAE model with the following inputs:

- y: direct estimates (in this case, log transformed)
- X: design matrix of covariates
- m: number of small areas (i.e., counties)
- G: the length of the chain
- beta: starting values for β
- a0: prior shape parameter for inverse-gamma distribution
- b0: prior scale parameter for inverse-gamma distribution
- sigma.sq.v: starting value for random effect variance

```

# Runs three chains for the Fay-Herriot (FH) SAE model
chain1 <- FH.model(y = logy, X = X, m = m,
                  sigma.sq = tilde.sigma.sq, G = G,
                  beta = beta.start,
                  a0 = 2, b0 = mean(tilde.sigma.sq),
                  sigma.sq.v = 1)

chain2 <- FH.model(y = logy, X = X, m = m,
                  sigma.sq = tilde.sigma.sq, G = G,
                  beta = as.matrix(c(1, -1, 1), nrow = 3),
                  a0 = 2, b0 = mean(tilde.sigma.sq),
                  sigma.sq.v = 0.1)

chain3 <- FH.model(y = logy, X = X, m = m,
                  sigma.sq = tilde.sigma.sq, G = G,
                  beta = as.matrix(c(10, -0.1, 0.1), nrow = 3),
                  a0 = 2, b0 = mean(tilde.sigma.sq),
                  sigma.sq.v = 0.5)

```

```
# a list combining the three chains
FH.chains <- list(chain1, chain2, chain3)
```

We now run three chains for the FHCAR SAE model with similar inputs to the FH model with the addition of the starting value for the autocorrelation parameter (λ) and the neighborhood matrix (R).

```
# Runs three chains for the FHCAR SAE model
chain1 <- FHCAR.model(y = logy, X = X, m = m,
  sigma.sq = tilde.sigma.sq, G = G, lambda = 0.5,
  beta = beta.start,
  a0 = 2, b0 = mean(tilde.sigma.sq),
  sigma.sq.v = 1, R = R)

chain2 <- FHCAR.model(y = logy, X = X, m = m,
  sigma.sq = tilde.sigma.sq, G = G, lambda = 0.8,
  beta = as.matrix(c(1,-1,1), nrow = 3),
  a0 = 2, b0 = mean(tilde.sigma.sq),
  sigma.sq.v = 0.1, R = R)

chain3 <- FHCAR.model(y = logy, X = X, m = m,
  sigma.sq = tilde.sigma.sq, G = G, lambda = 0.1,
  beta = as.matrix(c(10,-0.1,0.1), nrow = 3),
  a0 = 2, b0 = mean(tilde.sigma.sq),
  sigma.sq.v = 0.5, R = R)

# a list combining the three chains
FHCAR.chains <- list(chain1, chain2, chain3)
```

We can additionally output the chains for separate model summaries or continue with the summaries that follow.

```
# save output for summarizing the models
save(list = c("FH.chains", "FHCAR.chains"),
  file = paste(state, "-chains.RData", sep = ''))
```

Fay-Herriot (FH) Model Summary

Re-create objects `chain1`, `chain2`, `chain3` for the FH model.

```
# three chains of FH model
chain1 <- FH.chains[[1]]
chain2 <- FH.chains[[2]]
chain3 <- FH.chains[[3]]
```

The following creates the post burn-in samples for SAE parameters θ_i (`tsamps`), β (`bsamps`), σ_v^2 (`ssamps`), and the weighting between direct estimates and linking model (`gsamps`).

```
# MCMC samples
# Chain 1
theta.mat <- chain1[[1]]
beta.mat <- chain1[[2]]
sigma.sq.v.vec <- chain1[[3]]
g.mat <- chain1[[4]]

# Chain 2
theta.mat2 <- chain2[[1]]
```

```

beta.mat2 <- chain2[[2]]
sigma.sq.v.vec2 <- chain2[[3]]
g.mat2 <- chain2[[4]]

# Chain 3
theta.mat3 <- chain3[[1]]
beta.mat3 <- chain3[[2]]
sigma.sq.v.vec3 <- chain3[[3]]
g.mat3 <- chain3[[4]]

# mcmc objects
tsamps.list <- mcmc.list(mcmc(t(theta.mat[,sub])), mcmc(t(theta.mat2[,sub])),
                        mcmc(t(theta.mat3[,sub])))
bsamps.list <- mcmc.list(mcmc(t(beta.mat[,sub])), mcmc(t(beta.mat2[,sub])),
                        mcmc(t(beta.mat3[,sub])))
ssamps.list <- mcmc.list(mcmc(sigma.sq.v.vec[sub]), mcmc(sigma.sq.v.vec2[sub]),
                        mcmc(sigma.sq.v.vec3[sub]))
gsamps.list <- mcmc.list(mcmc(t(g.mat[,sub])), mcmc(t(g.mat2[,sub])),
                        mcmc(t(g.mat3[,sub])))

# Post burn-in samples
tsamps <- rbind(tsamps.list[[1]], tsamps.list[[2]], tsamps.list[[3]])
bsamps <- rbind(bsamps.list[[1]], bsamps.list[[2]], bsamps.list[[3]])
ssamps <- c(ssamps.list[[1]], ssamps.list[[2]], ssamps.list[[3]])
gsamps <- rbind(gsamps.list[[1]], gsamps.list[[2]], gsamps.list[[3]])

```

The posterior samples are now summarized for the posterior mean of θ_i (`theta.mean`), posterior median and 95% credible interval of θ_i (`theta.hat`); for the additional parameters of β , σ_v^2 , and weighting between direct estimates and linking model. The SAE parameter θ_i at individual county and state-level, as noted in code comments, is assessed by the following metrics: bias, mean squared error, root mean squared error, 95% empirical coverage rate, and 95% credible interval width.

```

# Summarize posteriors
theta.mean <- apply(exp(tsamps), 2, mean)
theta.mean <- round(theta.mean, digits = 0)

theta.hat <- apply(exp(tsamps), 2, quant)

beta.mean <- apply(bsamps, 2, mean)
beta.hat <- apply(bsamps, 2, quant)

sigma.sq.v.mean <- apply(as.matrix(ssamps), 2, mean)
sigma.sq.v.hat <- apply(as.matrix(ssamps), 2, quant)

gamma.hat <- apply(gsamps, 2, quant)

# bias
theta.bias <- round(theta.mean - Ytrue$Y.T, digits = 0)
y.bias <- round(dat.sub$Y.i - Ytrue$Y.T, digits = 0)

# Mean squared error (MSE) at state-level
theta.mse <- round(mean((theta.mean - Ytrue$Y.T)^2), digits = 0)
y.mse <- round(mean((dat.sub$Y.i - Ytrue$Y.T)^2), digits = 0)

```

```

# Root mean squared error (RMSE) at state-level
theta.rmse <- sqrt(theta.mse)
y.rmse <- sqrt(y.mse)

# coverage at state-level
state.cover <- sum(ifelse(Ytrue$Y.T >= theta.hat[2,] &
                          Ytrue$Y.T <= theta.hat[3,], 1, 0)) / m
state.cover <- round(100 * state.cover, digits = 1)

# 95% Credible interval widths for each county
theta.ciw <- round(theta.hat[3,] - theta.hat[2,], digits = 0)

```

The following figure assesses the accuracy of the direct estimates (black circles) and FH model estimates (light seagreen circles) against the GIS-derived true population.

Fay-Herriot Conditional Autoregressive (FHCAR) Model Summary

Overwrite the three chains of the FH model with the FHCAR chains.

```

# three chains of FH model
chain1 <- FHCAR.chains[[1]]
chain2 <- FHCAR.chains[[2]]
chain3 <- FHCAR.chains[[3]]

```

The following creates the post burn-in samples for SAE parameters θ_i (tsamps), β (bsamps), λ (lsamps), σ_v^2 (ssamps), and the Metropolis-Hastings acceptance (csamps).

```

# MCMC samples
# Chain 1

```

```

theta.mat <- chain1[[1]]
beta.mat <- chain1[[2]]
lambda.vec <- chain1[[3]]
sigma.sq.v.vec <- chain1[[4]]
count.vec <- chain1[[5]]

# Chain 2
theta.mat2 <- chain2[[1]]
beta.mat2 <- chain2[[2]]
lambda.vec2 <- chain2[[3]]
sigma.sq.v.vec2 <- chain2[[4]]
count.vec2 <- chain2[[5]]

# Chain 3
theta.mat3 <- chain3[[1]]
beta.mat3 <- chain3[[2]]
lambda.vec3 <- chain3[[3]]
sigma.sq.v.vec3 <- chain3[[4]]
count.vec3 <- chain3[[5]]

# mcmc objects
tsamps.list <- mcmc.list(mcmc(t(theta.mat[,sub])),
                        mcmc(t(theta.mat2[,sub])),
                        mcmc(t(theta.mat3[,sub])))
bsamps.list <- mcmc.list(mcmc(t(beta.mat[,sub])),
                        mcmc(t(beta.mat2[,sub])),
                        mcmc(t(beta.mat3[,sub])))
lsamps.list <- mcmc.list(mcmc(lambda.vec[sub]),
                        mcmc(lambda.vec2[sub]),
                        mcmc(lambda.vec3[sub]))
ssamps.list <- mcmc.list(mcmc(sigma.sq.v.vec[sub]),
                        mcmc(sigma.sq.v.vec2[sub]),
                        mcmc(sigma.sq.v.vec3[sub]))
count.list <- mcmc.list(mcmc(count.vec[sub]),
                       mcmc(count.vec2[sub]),
                       mcmc(count.vec3[sub]))

# Post burn-in samples
tsamps <- rbind(tsamps.list[[1]], tsamps.list[[2]], tsamps.list[[3]])
bsamps <- rbind(bsamps.list[[1]], bsamps.list[[2]], bsamps.list[[3]])
lsamps <- c(lsamps.list[[1]], lsamps.list[[2]], lsamps.list[[3]])
ssamps <- c(ssamps.list[[1]], ssamps.list[[2]], ssamps.list[[3]])
csamps <- c(count.list[[1]], count.list[[2]], count.list[[3]])

```

The posterior samples are now summarized for the posterior mean of θ_i (`theta.mean`), posterior median and 95% credible interval of θ_i (`theta.hat`); for the additional parameters of β , λ , σ_v^2 , and Metropolis-Hastings acceptance (`count.hat`). The SAE parameter θ_i at individual county and state-level, as noted in code comments, is assessed by the following metrics: bias, mean squared error, root mean squared error, 95% empirical coverage rate, and 95% credible interval width.

```

# Summarize posteriors
